## **Train CompNeuro Model**

### **Action Items:**

- train with all 108 numpy arrays resulting from Superglue alignment
  - this means to follow all the steps below with the full amt of arrays
- finish training the model with 50 numpy arrays Abinaya
  - figure out how to resume model from checkpoint

# make the dataset: convert our numpy arrays to rgba and save as png

1. take the **numpy arrays** of images that you want and put them in the aligned folder in the Sandbox directory

convert those numpy arrays to rgba using the npy\_rgba notebook, located in the Sandbox directory

```
{\sf Sandbox-Comp-Neuro} \ \geqslant \ {\sf npy\_rgba.ipynb} \ > \ \clubsuit \ {\sf files=os.listdir(path=path\_to\_arrays)}

                                                                                                                                                                                                                                                                                                                                                     + Code + Markdown
                                    from PIL import Image
                                   import numpy as np
                                   import os
                                     # make sure to replace this with your own path
                                   path_to_arrays = "/Users/abinayadinesh/Documents/Sandbox-Comp-Neuro/aligned"
   []
                                     files = os.listdir(path=path_to_arrays)
                                    counter = 0
                                    for file in files:
                                                   array = np.load(path_to_arrays + "/" + file)
                                                   print(array.shape)
                                                   img = Image.fromarray(array)
                                                  img.save(str(counter) + '.png')
                                                   counter += 1
  [15]
                        √ 1m 10.4s
                     (1232, 1640, 4)
```

Drag and drop the images that were outputted into the DIV2K folder

### train the model

PLEASE USE GPU'S, OR ELSE THIS WILL TAKE ALL DAY run the command: python3 main.py --ons\_dim 32 -nct 4

this will take all the images in DIV2K and batch them into a directory called DIV\_2K\_Cropped\_37 so we have a dataset of 50k images then it will automatically train the model on this dataset

#### evaluate

evalute using the color matching functions: python 2\_color\_matching.py

figures will be in results/cmf/model\_3\_tri\_32\_Cn\_0.01
